# 1982 Kentucky Small Grain Variety Trials

D. A. Van Sanford, V. C. Finkner, C. R. Tutt,  
W. H. Roberts, and K. M. Tichenor

In 1982, Kentucky produced 26.4 million bushels of soft red winter wheat. The yield average of 39 bu/a was down somewhat from the 1981 record of 42 bu/a. Acres of barley harvested did not change from 1981, but there was a yield decrease. Oat acreage remained the same in 1982 with a 3 bu/a increase in yield average over 1981.

Table 1.—Small Grain Harvested Acreage and Yields in Kentucky 1980-1982\*

Crop	1982		1981		1980	
	Harvest 1000 A	Yield Bu/A	Harvest 1000 A	Yield Bu/A	Harvest 1000 A	Yield Bu/A
Wheat	675	39	700	42	350	39

Oats	7	43	7	39	6	44
Rye	2	27	4	25	3	26

\*July 12, 1982, Kentucky Crop and Livestock Reporting Service

Small grain performance tests were conducted in six of the seven agroclimatic regions of Kentucky (Fig. 1). Agricultural areas within each region are considered to have similar soil types and climatic conditions. Each region having a substantial acreage of a small grain commodity will have a trial conducted in that region for that commodity.

Acknowledgement is made to William Green, Tom Curtsinger, Tom Amos, and Russell Lowe, county Extension agents for agriculture, for assistance in locating test sites and collecting data.

The objective of the Kentucky small grain variety trials is to evaluate varieties of barley, wheat, and oats that are commercially available or may soon be available to Kentucky farmers. New varieties are continually being developed by agricultural experiment

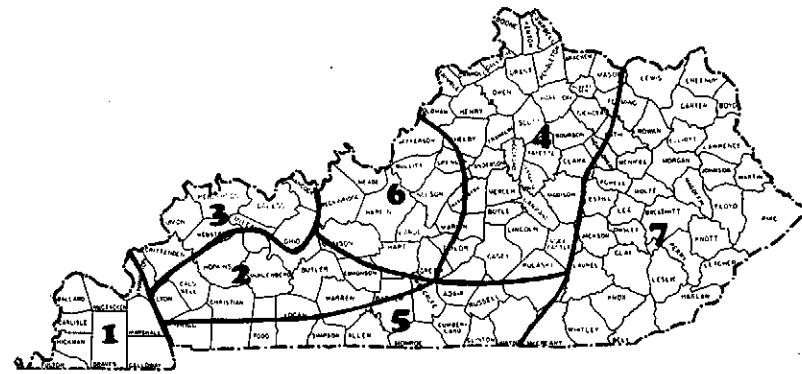

Figure 1.—Agro-climatic regions of Kentucky small grain variety trials.

Region	1982 Location	Cooperator	Crop Tested
1 Purchase	Mayfield	Mr. Paul Payne	Wheat
2 Western Coal Field	Princeton (Sandstone soil)	Research & Education Center—Princeton	Barley, Wheat
3 Ohio Valley	Owensboro	Miles Farm Supply	Wheat
4 Bluegrass	Lexington	Kentucky Agricultural Experiment Station	Barley, Winter Oats, Wheat, Spring oats
5 Southern Tier	Hopkinsville Princeton (Limestone soil)	Mr. Harry Young Research & Education Center—Princeton	Barley, Wheat Barley, Winter Oats, Wheat
6 North Central	Greensburg	Mr. William Henderson	Wheat

stations and commercial firms. Annual evaluation of small grain varieties and selections provides seedsmen, farmers, and other agricultural workers with current information to help them select the varieties best adapted to their locality and individual requirements.

Since weather, soil and other environmental factors will alter varietal performance from one location to another, tests are grown in six locations (Fig. 1) in the state. Suggested varieties are revised each year because of the availability of new varieties, improvements in production practices, and continually changing disease and insect hazards.

## EXPERIMENTAL METHODS

The plots were planted with a specially built multi-row cone seeder. Each plot consisted of four or six rows to form a plot 4 feet wide, which was later trimmed to 10 feet in length. Each variety was grown in four replications, and the data presented are the average response from the four replications of 40 square feet harvested with a small plot combine. Planting dates of all trials for the past 3 years are listed in Table 2.

In some instances, uncontrollable factors—such as excessive rainfall, winter killing, high winds, hail, grazing cattle, etc.—adversely affected an experiment so that the results were judged unreliable. When this occurred, results are not given for that location and year. Data averaged over a period of years gives a more accurate picture of varietal performance than does annual data.

## DATA COLLECTED

It is important to consider other characteristics in addition to grain yield when selecting a variety.

Grain yield of plots was taken by cutting all rows with a self-propelled combine. The weights of each plot were recorded in grams and converted to bushels per acre.

Test weight, or the weight of a bushel of grain, is a measure of the quality of the grain. The higher the test weight, the higher the quality and market value, unless the grain has been down-graded because of another quality factor.

**Table 2.—Region, Location, Preceding Crop and Planting Dates of Kentucky Small Grain Trials 1980-82**

Region	Location	Preceding Crop	Crop	Planting Date		
				1982	1981	1980
Purchase	Mayfield	Soybeans	Wheat	10/30	10/22	10/17
Western Coal Field	Princeton (Sandstone soil)	None	Barley Winter Oats Wheat	10/14	10/6	10/16

				3/29	4/3	4/3
				10/22	10/9	10/15
Southern Tier	Hopkinsville	Corn	Barley Wheat	10/15	10/10	10/18
	Princeton (Limestone soil)	None	Barley Winter Oats Wheat	10/6	10/7	10/11
				10/6	10/7	10/11
				11/2	10/16	10/11
North Central	Elizabethtown (1980-81) Greensburg (1982)	Corn Soybeans	Barley Wheat	—	10/15	10/18
				10/21	—	—

Lodging was recorded as the percentage of the total plants lying on the ground or leaning at a 45-degree angle from the vertical when the grain was mature. The term "maturity" as used in this report refers to the date the grain was ready to be combine harvested.

Plant height was recorded as the number of centimeters from the ground to the tip of the upright grain head, and converted to inches.

Survival was recorded as the percentage of plants estimated to have survived the winter. This is a measure of winterhardiness and is an important factor to consider when selecting a variety.

Heading date is reported as the date when 50% of the heads had emerged from the plants in each plot. This is also a measure of maturity and is important when selecting a variety for use in a double-cropping system.

Disease and insect data are reported as relative amounts that occurred on the varieties at the time the readings were made. Disease and insect problems are often different in different years.

## RESULTS AND DISCUSSION

Since genetic expression of a variety is greatly influenced by environmental conditions, it is best to have several years' data from which to draw conclusions. Performance of a variety tested for only one year should not be compared with a 3-year average of another variety, since it is possible that results in one of the other years were extremely good or poor, and thus not comparable.

The yield of a variety is relative and should be compared with the yields of the other varieties in the same experiment and at the same location. Small differences in yield of only a few bushels per acre between two varieties from an individual test should not be interpreted to indicate the superiority of one variety over another. However, if one variety consistently out-yields another over a period of several years, the chances are that the differences are real.

Lodging data are very difficult to interpret. A high-yielding variety should not necessarily be down-graded because of a high percentage of lodging for a given year and at a given location. Local weather conditions, such as wind and rain, may cause a variety to lodge much more than it normally does. Variety trials normally have a greater degree of lodging than do farmer fields. It should also be emphasized that a variety reported to be 50% lodged does not imply that only 50% of the grain could be harvested. With good equipment, almost all of the grain can often be saved. Lodging data for a period of years should receive more consideration than annual lodging data since they will give a more accurate picture of varietal performance.

## 1982 TEST CONDITIONS

Seeding of the 1982 crop was completed on schedule at most locations. Mild fall conditions with adequate moisture allowed for good stand establishment and plant development in all tests.

Record low temperatures were observed across the state in January. In the absence of adequate snow cover, more winterkill than normal occurred. Winter oats were very severely damaged across the state, while winterkill of barley and wheat was considerably less.

A hard freeze occurred in April after wheat had begun to joint and barley was approaching the boot stage in the southern part of the state. While some injury to spikes resulted from this late freeze, damage was much less extensive than expected.

The cool, late spring provided favorable conditions for disease development. There were severe infestations of powdery mildew and leaf rust which began in the Purchase Area and the Southern Tier and moved north and east. As a result of this heavy disease pressure, yields and test weights of wheat were lower than those in 1981.

In addition, the disease conditions contributed to the variability in varietal performance across locations.

## 1981 TEST CONDITIONS

Favorable weather prevailed during the fall of 1980 and seeding of the 1981 crop was completed by a near normal date. The winter was unusually mild, and consequently little winterkill was observed. Early warming in the spring hastened the maturity of the small grain crops, and heading dates considerably earlier than usual were recorded. Little spring freeze damage occurred, however. Above average precipitation in June, followed by periods of strong winds, resulted in severe lodging in certain areas of the state. The harvest dates of the 1981 crop were earlier than usual, and the harvest was completed without undue delay.

Heavy infestation of the head scab fungus and *Septoria glume blotch* were responsible for lower test weights and overall reduction in seed quality. Powdery mildew was in evidence, as were tan spot and loose smut. Little yield loss was attributed to these diseases.

## 1980 TEST CONDITIONS

The 1980 crop was seeded at near normal times and conditions in the fall of 1979. The winter season was also near normal with very

little winter killing. Unseasonably warm temperatures did occur for several days in January and February, but the small grain plants maintained their winter-hardened condition and survived subsequent cold weather. Heading dates were earlier than normal, but spring freeze damage did not occur. Cooler than normal temperatures in May and June helped to alleviate below normal precipitation. Harvest was accomplished without unusual weather related delays.

Head scab disease caused considerable damage to late heading wheat. Scab was most severe in wheat planted in no-till corn fields where the above-ground corn residue served as a scab scourge. Barley yellow dwarf, wheat leaf rust, wheat spindle streak mosaic virus, wheat mildew, and barley scald were observed but caused minimal yield losses. Again this year, the cereal leaf beetle continued to expand its territory but caused little yield loss.

## SMALL GRAIN VARIETIES FOR 1983

Varieties eligible for certification include (1) varieties that may have potential for Kentucky and (2) older varieties that are still acceptable for production in Kentucky. The characteristics of the small grain varieties are summarized in Tables 3 and 10.

### Soft Red Winter Wheat Varieties

Kentucky's climate and soils are well suited for the production of high quality soft red winter wheat. No single variety has all the desirable characteristics, but each has certain advantages. Yielding ability, straw strength, height, earliness, grain quality, and disease resistance are important in choosing a variety. Varietal performance is presented in Tables 4-9. Arthur and Abe have long been the most widely grown varieties, although 1982 saw a marked increase in the acreage planted to Hart.

The susceptibility of Hart to powdery mildew lowered its yield and test weight in many areas of the state in 1982. Wheeler, a variety developed in Virginia, is well adapted to growing conditions in Kentucky and has performed well in two years of testing.

### Winter Barley Varieties

Winter barleys are less winterhardy than winter wheat but more hardy than winter oats. The degree of winterhardiness, straw strength, and maturity are important characteristics when choosing a variety. Varietal performance data are presented in Tables 11-13A. Varieties now commonly grown are Barsoy and Volbar.

### Winter Oat Varieties

Winter oats are the least winterhardy of the winter grains. Early seeding, good fertilization practices, and planting on well-drained soils are recommended to minimize winter killing. Winter oats are also excellent for grazing and silage. Performance of the winter oat varieties is presented in Tables 14-16. Varieties now commonly grown are Compact, Norline and Walken. The variety Kenoat, formerly tested as KY 67-695, was released by the University of Kentucky in 1981.

### Spring Oat Varieties

The only small grain suitable for spring seeding by farmers in Kentucky is spring oats. Spring oats are used mainly for hay or silage, and as a companion crop for grasses and legumes. Grain and forage yields of spring oats are lower than those of the winter oat varieties when yields of winter oats are not severely reduced from winter killing or disease. Two spring oat varieties (Otee and Jaycee) are commonly grown because of their higher level of resistance to Barley Yellow Dwarf Virus (oat red leaf). Performance data are listed in Table 17.

### CERTIFIED SEED

Planting certified seed is one of the first steps in ensuring a good small grain crop. The extra cost of certified seed is justified in view of the high quality of seed obtained. Certified seed is seed which has been grown in such a way as to ensure the genetic identity and purity of a variety. Certified seed also helps to maintain freedom from weed and other crop seed and, in some cases, freedom from disease. The Kentucky Agricultural Experiment Station recommends that Kentucky-certified seed be used whenever possible for growing commercial crops of small grains.

CV = 13.5%<sup>1/</sup>

LSD = 3.4 Bu<sup>2/</sup>

<sup>1/</sup> The CV is a measure of experimental error. The lower the CV, the more reliable the results.

<sup>2/</sup> The LSD (Least Significant Difference) is the minimum difference in yields required for two varieties to be significantly different from one another.

<sup>3/</sup> "Unauthorized propagation prohibited." Seed of these varieties must be sold by variety name only as a class of certified seed. This includes varieties for which protection has been applied and those for which protection has been granted.
