1984 Kentucky Small Grain Variety Trials

D. A. Van Sanford, C. R. Tutt,
W. H. Roberts and C. S. Swanson

In 1984, Kentucky farmers harvested 18 million bushels of soft red winter wheat produced on 500,000 acres. The average yield of 36 bu/a was up from the 1983 average of 35 bu/a. Barley production was up 45% from 1982 levels with a yield average of 40 bu/a.

*July 1, 1984, Kentucky Crop and Livestock Reporting Service

Small grain performance tests were conducted in six of the seven agroclimatic regions of Kentucky (Fig. 1). Agricultural areas within each region are considered to have similar soil types and climatic conditions. Each region having a substantial acreage of a small grain commodity will have a trial conducted in that region for that commodity.

Acknowledgement is made to the following individuals for their contributions to the bulletin: Larry Reber, John Hancock, Tom Curtsinger, Rodney Haines, Tommy Harrison and Russell Lowe, County Extension Agents for Agriculture, for assistance in locating test sites and collecting data; R. E. Stuckey and D. Hershman for disease ratings; J. Byars for data analysis; J. Carey for text and table preparation.

The objective of the Kentucky small grain variety trials is to evaluate varieties of barley and wheat that are commercially available or may soon be available to Kentucky farmers. New varieties are continually being developed by agricultural experiment stations

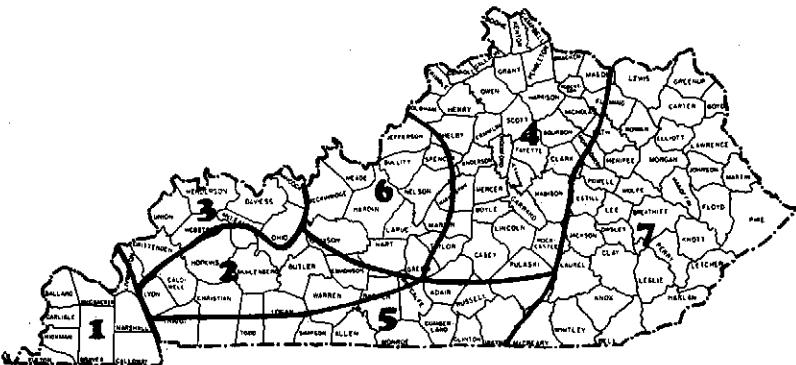

Figure 1.—Agro-climatic regions of Kentucky small grain variety trials.

Region	1984 Location	Cooperator	Crop Tested
1 Purchase	Hickman	Joe & Joe F. Campbell	Wheat
2 Western Coal Field	Princeton (Sandstone soil)	Research & Education Center—Princeton	Barley, Wheat
3 Ohio Valley	Owensboro	Miles Farm	Wheat
4 Bluegrass	Lexington	Kentucky Agricultural Experiment Station	Barley, Wheat
5 Southern Tier	Russellville Princeton (Limestone soil)	Eddy Russell Research & Education Center—Princeton	Barley, Wheat Barley, Wheat
6 North Central	Greensburg	William Henderson	Wheat

and commercial firms. Annual evaluation of small grain varieties and selections provides seedsmen, farmers, and other agricultural workers with current information to help them select the varieties best adapted to their locality and individual requirements.

Since weather, soil and other environmental factors will alter varietal performance from one location to another, tests are grown in six locations (Fig. 1) in the state. Suggested varieties are revised each year because of the availability of new varieties, improvements in production practices, and continually changing disease and insect hazards.

EXPERIMENTAL METHODS

The plots were planted with a specially built multi-row cone seeder. Each plot consisted of six rows to form a plot 4 feet wide, which was later trimmed to 10 feet in length. Each variety was grown in four replications, and the data presented are the average response from the four replications of 40 square feet harvested with a small plot combine. Planting dates of all trials for the past 3 years are listed in Table 2.

In some instances, uncontrollable factors—such as excessive rainfall, winter killing, high winds, hail, grazing cattle, etc.—adversely affected an experiment so that the results were judged unreliable. When this occurred, results are not given for that location and year. Data averaged over a period of years gives a more accurate picture of varietal performance than does annual data.

DATA COLLECTED

It is important to consider other characteristics in addition to grain yield when selecting a variety.

Grain yield of plots was taken by cutting all rows with a self-propelled combine. The weights of each plot were recorded in grams and converted to bushels per acre.

Test weight, or the weight of a bushel of grain, is a measure of the quality of the grain. The higher the test weight, the higher the quality and market value, unless the grain has been down-graded because of another quality factor.

Table 2.—Region, Location, Preceding Crop and Planting Dates of Kentucky Small Grain Trials, 1982-84.

Region	Location	Preceding Crop	Crop	Planting Date

North Central	Greensburg	1982-84 Soybeans	Wheat	10/28	11/01	10/21						

Lodging was recorded as the percentage of the total plants lying on the ground or leaning at a 45-degree angle from the vertical when the grain was mature. The term "maturity" as used in this report refers to the date the grain was ready to be combine harvested.

Plant height was recorded as the number of centimeters from the ground to the tip of the upright grain head, and converted to inches.

Survival was recorded as the percentage of plants estimated to have survived the winter. This is a measure of winterhardiness and is an important factor to consider when selecting a variety.

Heading date is reported as the date when 50% of the heads had emerged from the plants in each plot. This is also a measure of maturity and is important when selecting a variety for use in a double-cropping system.

Disease and insect data are reported as relative amounts that occurred on the varieties at the time the readings were made. Thus, differences in varietal ratings may reflect factors such as maturity, as well as genetic differences in disease resistance.

RESULTS AND DISCUSSION

Since genetic expression of a variety is greatly influenced by environmental conditions, it is best to have several years' data from which to draw conclusions. Performance of a variety tested for only one year should not be compared with a 3-year average of another variety, since it is possible that results in one of the other years were extremely good or poor, and thus not comparable.

The yield of a variety is relative and should be compared with the yields of the other varieties in the same experiment and at the same location. Small differences in yield of only a few bushels per acre between two varieties from an individual test should not be interpreted to indicate the superiority of one variety over another. However, if one variety consistently out-yields another over a period of several years, the chances are that the differences are real.

Lodging data are very difficult to interpret. A high-yielding variety should not necessarily be down-graded because of a high percentage of lodging for a given year and at a given location. Local weather conditions, such as wind and rain, may cause a variety to lodge much more than it normally does. Variety trials normally have a greater degree of lodging than do farmer fields. It should also be emphasized that a variety reported to be 50% lodged does not imply that only 50% of the grain could be harvested. With good equipment, almost all of the grain can often be saved. Lodging data for a period of years should receive more consideration than annual lodging data since they will give a more accurate picture of varietal performance.

1984 TEST CONDITIONS

An extremely dry summer in 1983 followed by an unusually wet October delayed seeding of small grains across the state.

Cold, wet weather prevailed in November and early season growth of wheat and barley was minimal. Sub-zero temperatures

were recorded across the state in late December and early January. The absence of insulating snow cover during this period resulted in substantial winterkill of both barley and wheat. A freeze in late March also contributed to winter injury in these crops. Winterkill was so severe in barley test plots that no results are reported for 1984 (Tables 11-14A).

A late cool spring slowed growth of the wheat crop so that heading dates were later than usual. Poor spring growth and reduced stands due to winterkill created severe weed problems for many farmers.

Disease pressure was less intense in 1984 than in previous years. Powdery mildew was observed late and generally was not a problem. Septoria leaf blotch was abundant but was not believed to affect yields significantly. Leaf rust was present in most locations and where infection occurred early in the grain filling period, yields and test weights were reduced. Stem rust, caused by a different pathogen than leaf rust, was observed in significant numbers for the first time in Kentucky in 1984. Disease ratings for 2 locations are presented in Table 10.

1983 TEST CONDITIONS

Mild fall weather permitted planting of the 1982 crop to be completed on schedule.

Unusually warm temperatures prevailed through the fall and early winter. Lush growth of small grains was observed during this period and winterkill was essentially nonexistent. These mild conditions allowed for a heavy infestation of aphids, which can transmit barley yellow dwarf virus. Fungal pathogens which do not normally overwinter in Kentucky were able to survive the winter of 1982-83.

The mild winter was followed by a late cool spring with excessive precipitation. This combination of winter and spring conditions created an environment ideal for diseases of small grains.

Barley yellow dwarf virus was severe in the central and southern tier regions of the state. The severity of the disease is reflected in the low average yield of barley across the state (38 bu/a).

Wheat was affected by the yellow dwarf virus, but also had to contend with wheat spindle streak mosaic virus, powdery mildew,

leaf blotch, leaf rust, glume blotch, and head scab. The highest levels of head scab observed in years were seen in 1983.

1982 TEST CONDITIONS

Seeding of the 1982 crop was completed on schedule at most locations. Mild fall conditions with adequate moisture allowed for good stand establishment and plant development in all tests.

Record low temperatures were observed across the state in January. In the absence of adequate snow cover, more winterkill than normal occurred. Winter oats were very severely damaged across the state, while winterkill of barley and wheat was considerably less.

A hard freeze occurred in April after wheat had begun to joint and barley was approaching the boot stage in the southern part of the state. While some injury to spikes resulted from this late freeze, damage was much less extensive than expected.

The cool, late spring provided favorable conditions for disease development. There were severe infestations of powdery mildew and leaf rust which began in the Purchase Area and the Southern Tier and moved north and east. As a result of this heavy disease pressure, yields and test weights of wheat were lower than those in 1981.

In addition, the disease conditions contributed to the variability in varietal performance across locations.

SMALL GRAIN VARIETIES FOR 1985

Varieties eligible for certification include (1) varieties that may have potential for Kentucky and (2) older varieties that are still acceptable for production in Kentucky. The characteristics of the small grain varieties are summarized in Tables 3 and 11.

Soft Red Winter Wheat Varieties

Kentucky's climate and soils are well suited for the production of high quality soft red winter wheat. No single variety has all the desirable characteristics, but each has certain advantages. Yielding ability, straw strength, height, earliness, grain quality, and disease resistance are important in choosing a variety. Varietal performance is presented in Tables 4-9.

Arthur and Abe were the most widely grown varieties for many years. With the development of higher yielding varieties adapted to Kentucky, that picture is changing.

Winter Barley Varieties

Winter barleys are less winterhardy than winter wheat but more hardy than winter oats. The degree of winterhardiness, straw strength, and maturity are important characteristics when choosing a variety. Varietal performance data are presented in Tables 12-14A. Varieties now commonly grown are Barsoy and Pike.

CERTIFIED SEED

Planting certified seed is one of the first steps in ensuring a good small grain crop. The extra cost of certified seed is justified in view of the high quality of seed obtained. Certified seed is seed which has been grown in such a way as to ensure the genetic identity and purity of a variety. Certified seed also helps to maintain freedom from weed and other crop seed and, in some cases, freedom from disease. The Kentucky Agricultural Experiment Station recommends that Kentucky-certified seed be used whenever possible for growing commercial crops of small grains.

CV = 15%^{1/}
LSD (.05) = 4 Bu/A^{2/}

^{1/} The CV is a measure of experimental error. The lower the CV, the more reliable the results.

^{2/} The LSD (Least Significant Difference) is the minimum difference in yields required for two varieties to be significantly different from one another.

^{3/} "Unauthorized propagation prohibited." Seed of these varieties must be sold by variety name only as a class of certified seed. This includes varieties for which protection has been applied and those for which protection has been granted.
