Acknowledgments

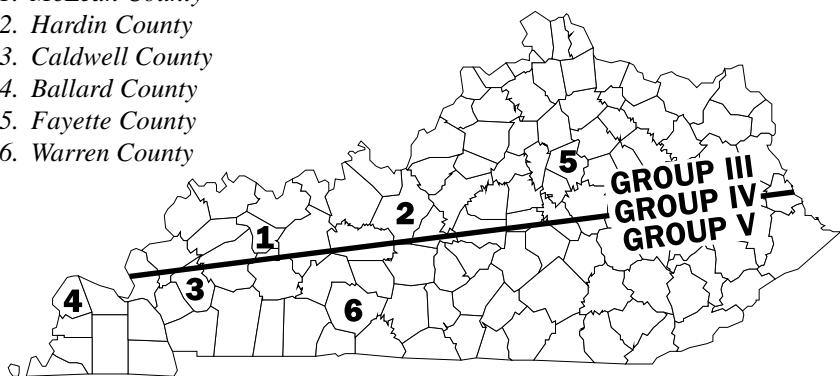

In addition to the county agents and farm cooperators mentioned in Table 1, David Pilcher and Julie Scollin have contributed greatly to the production of this publication.

The Kentucky Soybean Performance Tests are conducted to provide an unbiased, objective estimate of the relative performance of soybean varieties in Kentucky. This information may be used by growers and seedsmen to aid in selecting varieties that will give the highest total production in a specific situation.

Eight soybean tests were planted in 1996 in Kentucky. The testing locations are shown below. Soil types, planting dates, and other information are shown in Table 1.

Location of the 1996 Kentucky Soybean Tests

1. *McLean County*
2. *Hardin County*
3. *Caldwell County*
4. *Ballard County*
5. *Fayette County*
6. *Warren County*

Methods

All tests were planted in a randomized complete block design with two replications (plots) of each variety. In the conventional tests, individual plots were 20 feet long and 4 rows wide with 30 inches between rows. In the double-crop tests, the plots were 20 feet long and 6 rows wide with 15 inches between rows. The seeding rate for the conventional tests was 8 to 10 viable seeds per foot of row, and for the double-crop tests was 5 to 6 viable seeds per foot of row. All plots were planted with a modified soybean planter. All plots were treated with herbicides and maintained as weed-free as possible.

One test (SCN test in McLean Co., three replications) was planted at a site infested with soybean cyst nematode. Only varieties with some genetic resistance to SCN and susceptible check varieties were tested at this site.

Harvesting was done with a small plot combine according to maturity; thus, several harvests were made at each location. Sixteen feet of the center rows were harvested from the plots. No allowances were made for soybeans that may have been lost because of combining or shattering.

Yield—Yield is reported in bushels per acre adjusted to 13 percent moisture.

Lodging—Lodging is rated on a scale of 1 to 5, where 1 = almost all plants erect; 2 = all plants over slightly or a few down; 3 = all plants over moderately or 25 percent down; 4 = all plants over considerably or 50 to 80 percent down; 5 = all plants over badly.

Maturity date—A variety is considered mature when 95 percent of the pods had turned their normal mature color. One to two weeks of good drying weather will be needed beyond the date given before the beans will be ready to combine. Maturity dates were recorded at the Fayette Co., Ballard Co., and Caldwell Co. locations.

Plant height—Plant height was measured in inches from the soil surface to the tip of the main stem.

Pod height—Height of the lowest pod was measured in inches from the soil surface to the point of attachment of the lowest pod on the plant.

TABLE 1. LOCATION, PLANTING DATA, AND CLIMATIC DATA FOR THE 1996 SOYBEAN PERFORMANCE TESTS.

¹ No-till double cropped after wheat.² Amount per acre.³ Based on 30 year average

Soybean cyst nematode (SCN)—SCN populations were determined at planting and at harvest by measuring SCN egg densities in plots. Egg densities, reported as the number of eggs/100 cubic centimeters of soil (about 1/4 pint of soil), were determined from soil samples consisting of ten 6-inch deep soil probes from the center two rows of each plot. Soil was thoroughly mixed. Cysts were extracted from two 100-cubic-centimeter soil samples from each plot by wet sieving. Eggs were freed from cysts by crushing the cysts. Eggs were then stained and counted. The two egg counts from each plot were averaged to give a single egg density per plot. This data was provided by Don Hershman and Debbie Morgan of the Soybean Cyst Nematode Laboratory at Princeton, Kentucky.

Interpretation

An important step in profitable soybean production is selecting good quality seed of the best varieties for your management system. The Kentucky Soybean Performance Tests are conducted to provide information useful in making this selection.

Performance of soybean varieties is affected by many factors including year, location, soil type and time of planting. A particular soybean variety is adapted for full-season growth in a band approximately 100 miles wide from north to south. (Map, page 1) Thus, the best variety in northern Kentucky may not be the best in southern areas. For this reason the Kentucky Soybean Performance Tests are conducted at several locations in the major soybean producing areas of the state. The

yields as reported in this publication should be used for relative comparisons; actual yields on a grower's farm may be different.

Performance of the soybean varieties will vary from year to year and location to location depending on adaptability, weather conditions, and management. The performance data presented in Tables 3 and 4 have been averaged across years and locations. Performance of a variety across a period of years and at several locations in the state is the best indicator of its production potential. (See *Agronomy Notes*, Volume 21, No. 3, "Using Performance Test Results in Soybean Variety Selection in Kentucky.")

Small differences in yield are usually of little importance. The yield of two varieties at a single location may differ because of chance factors (difference in soil characteristics, fertility, or availability of moisture) although the inherent yielding ability is the same. To decide if an observed yield difference is real, use the LSD (least significant difference) values cited at the bottom of the tables. The significance level used in the tables is 0.10. If the difference in yield is greater than the LSD value, you may be reasonably certain that the entries actually do differ in yielding ability. "N.S." in the tables indicates that no statistically significant differences were determined.

Yield is only one factor to consider in selecting a variety for your production system. Maturity, lodging resistance, disease resistance, and time and equipment availability are other factors that need to be considered.

The data provided have been divided into maturity groups. Due to weather patterns at a location, maturity alone can affect yield; this will be reflected by large differences in the maturity group averages. Selecting varieties from several maturity groups can reduce the impact of these maturity group fluctuations. (See *Agronomy Notes*, Volume 25, No. 3, "Growing Soybean Varieties from Multiple Maturity Groups Can Reduce Yearly Yield Volatility.")

The date of a 50 percent chance of a fall killing frost is important in determining which variety you select to plant. The dates presented in Table 1 are average dates over a long term. Actual dates will vary from year to year. For the date of a one year out of ten chance of a fall killing frost, subtract 13-18 days from the dates in Table 1. For maximum yield, a variety must mature before the first killing frost in the fall. Maturity dates of varieties are listed for the Fayette Co., Ballard Co., and Caldwell Co. locations, and in the combined summary (Table 3).

If you have a soybean cyst nematode (SCN) problem, a resistant variety should be used in your production system with a recommended crop rotation program. (See Kentucky Cooperative Extension Service publication PPA-3, "Soybean Cyst Nematode," available at your County Extension office.) The level of SCN infestation as well as the SCN race can be determined through the SCN laboratory at Princeton. Contact your County Extension office for more information on collecting and submitting samples. The importance of resistant varieties has increased as the number of acres affected by SCN has increased. When evaluating the performance of resistant varieties in the SCN infested location, note the change in cyst numbers as well as the yield presented in this table.

Growing Conditions

Wet soil conditions early in the growing season delayed planting dates at all conventional locations. Inadequate soil moisture reduced emergence in one replication of the Princeton double-crop test; data from this replication were discarded. Inadequate summer rainfall reduced growth at the McLean Co. conventional test where canopy closure did not occur.

Soybean Production Information

The Kentucky Cooperative Extension Service has a series of publications, "Soybean Production in Kentucky," which contain a more detailed discussion of soybean production practices: Part I. Status, Uses, and Planning (AGR 128); Part II. Seed Selection, Variety Selection, and Fertilization (AGR 129); Part III. Planting Practices and Double Cropping (AGR 130); and Part IV. Weed, Disease, and Insect Control (AGR 131). A soybean planting rate guide, reproduced from this series, is provided for your convenience (Table 2).

Oil and Protein Data

The average protein and oil concentration for all soybean varieties entered in the Kentucky Soybean Performance Tests is presented in Table 12. The Federal Grain Inspection Service is offering soybean oil and protein testing as official criteria for grade. At this time the testing is optional. Soybean varieties differ in their protein and oil concentrations, which are influenced by the production environments. Because soybeans are grown primarily for oil and protein, these data are provided to indicate differences that exist between varieties produced in Kentucky.

Kentucky State Seed Law

The Kentucky state seed law requires all seed exposed, offered for sale, or sold in Kentucky to be labeled as to kind and variety for each agricultural seed component present in excess of 5 percent of the whole and the percentage by weight of each component. All soybean seed blends should be labeled as to the percentage of each variety that makes up the mixture. The term "variety unknown" may no longer be used in place of a variety designation for soybeans, as all soybean seed must be labeled by variety name.

^A PI/PI represents relative SCN reproduction during the growing season. Changes in SCN populations are best gauged by following SCN egg development through the season; cyst numbers only provide an estimate of population change. PI is the SCN egg count at the end of the season. PI is the number of eggs present at planting. A ratio of 1 indicates no additional SCN development relative to the population at planting. A ratio of less than 1 indicates a population decrease during the growing season (Example: a ratio of 0.1 indicates a 10-fold population decrease). A ratio of greater than 1 indicates a population increase (Example: a ratio of 5.0 indicates a 5-fold population increase).

^B Resistance to cyst nematode races are indicated for race 3 and race 14, the predominant races in Kentucky.
SUS - susceptible to SCN
ALL - Hartwig was developed using a different source of SCN resistance which, so far, provides resistance to all known races of SCN.

Note: Yield loss in soybeans caused by SCN is determined by the SCN population at planting - not the population at harvest.
A race test indicated that the field was infested with SCN Race 3.

^A Variety protein and oil concentration means were determined across the Fayette Co., Hardin Co., and Warren Co. locations and expressed on the basis of 13% moisture. The mean protein concentration was 35.6%, and the mean oil concentration was 17.4%. Significant differences existed among locations and among varieties. The LSD (0.10) among varieties was 0.9% for protein and 0.5% for oil.

* Resistant to the cyst nematode (Race 3)

** Resistant to the cyst nematode (Race 3 and Race 14)
