

2006 Kentucky Small Grain VARIETY PERFORMANCE TEST

B. Bruening, C. Tutt, C.S. Swanson, J. Connelley, G. Olson, N. Mundell, and D. Van Sanford

www.uky.edu/ag/WheatVarietyTest

The 2006 wheat growing season ended with Kentucky farmers harvesting 310,000 acres of soft red winter wheat and a total production of 21,080,000 bushels of grain. An average yield of 68 bushels per acre was recorded, which tied last years' state record (Table 1).

Small grain performance tests were conducted in six of the seven agroclimatic regions of Kentucky (Table 2). Agricultural areas within each region are considered to have similar soil types and climatic conditions. Each region having a substantial acreage of a small grain commodity had at least one trial conducted in that region for that commodity.

The objective of the Kentucky small grain variety performance test is to evaluate varieties of wheat and barley that are commercially available or may soon be available to Kentucky farmers. New varieties are continually being developed by agricultural experiment stations and commercial firms. Annual evaluation of small grain varieties and selections provides farmers, seed producers, and other agricultural workers with current information to help them select the varieties best adapted to their locality and individual requirements.

Because weather, soil, and other environmental factors may alter varietal performance from one location to another, eight tests (five conventional tillage and three no-till) were grown at seven locations throughout the state (Table 2). Additionally, tests for varietal differences in forage potential and straw yields were conducted at one location.

Experimental Methods

Seventy-two entries were evaluated under both conventional and no-till cultural practices. No-till tests were grown at three locations and conventional tests were grown at five locations. The experimental design was a randomized complete block. The tests had four replications per entry, and the data presented are the average response from the four replications.

The plots were planted with specially built multirow conventional and no-till cone seeders. Conventional test plots consisted of six rows to form a plot 4 feet wide and 15 feet long, which was later trimmed to 10 feet in length. No-till plots consisted of seven rows to form a plot 5 feet wide and 25 feet long, which was later trimmed to 20 feet in length. Plots were harvested with a small plot combine.

Table 1. Wheat harvested (1,000 acres) and yields (bu/acre) in Kentucky, 2004-2006.*

2006		2005		2004	
Harvested	Yield	Harvested	Yield	Harvested	Yield
310	68	300	68	370	55

*July 1, 2006, National Agricultural Statistics Service

Tests were conducted using intensive management practices. Typical herbicide applications included a spring application for broadleaf control and a fall preplanting burn-down (no-till tests only) application. Fungicides were applied in the spring on all but two (disease rating) tests. An insecticide for aphid control was typically applied in the fall and spring. Nitrogen was applied in a February/March split application at a rate of approximately 30/60 lbs/A (conventional tests) or 35/70 lbs/A (no-till).

Table 2. Agroclimatic regions of Kentucky small grain variety tests.

Region	Location	Cooperator	Crop Tested
1. Purchase	Calloway Co.	Marty Carraway	No-till Wheat
2. Western Coal Field	Caldwell Co.	Princeton Research and Education Ctr.	Wheat*, No-till Wheat, Barley
3. Ohio Valley	Webster Co.	Bruce Benson	Wheat*
4. Bluegrass	Fayette Co.	KY Agri. Expt. Station	Wheat*, Forage test
5. Southern Tier	Logan Co. Todd Co.	Don Halcomb Andy Gray	Wheat*, Barley Wheat*
6. North Central	Shelby Co.	Doug Langley	No-till Wheat

* Conventional tillage

The forage test was planted using conventional tillage and was harvested using a small plot forage combine at the beginning of the heading stage. Dry matter forage yield and crude protein content were determined. Straw yield was recorded using a small plot forage combine following grain harvest at the Bluegrass Region test.

Characteristics Evaluated

Grain yields were calculated from the weight of grain from each plot and reported in bushels per acre (bu/A) based on a 60-lb standard bushel weight at 13.5% moisture content. Test weights (pounds per bushel) were determined using standard test weight equipment. Lodging and winter survival were reported as the percentage of plant lodging at maturity or survival after spring green-up, respectively. Plant height was measured in inches from the soil surface to the top of the grain head. Heading dates were reported as the day an estimated 50% of the heads had extended above the flag leaf collar. Disease ratings (wheat streak mosaic virus, leaf rust, powdery mildew) were recorded from two conventional nonfungicide tests (Fayette and Caldwell counties), and head scab ratings were recorded at the Fayette and Caldwell county Fusarium head blight nurseries. Forage and straw yields are expressed as dry matter in tons per acre.

Results and Interpretation

Since genetic expression of a variety is greatly influenced by environmental conditions, it is best to have several years' data at multiple locations from which to draw conclusions. Performance of a variety tested for only one year should not be compared with a three-year average of another variety because it is possible that results in one of the other years were extremely good or poor and, thus, not comparable.

The yield of a variety is relative and should be compared with the yields of the other varieties in the same experiment and at the same location or within the same analysis across locations. Small differences in yield of only a few bushels per acre between two varieties from an individual test should not be interpreted to indicate the superiority of one variety over another. However, if one variety consistently out yields another over a period of several years, the chances are that the differences are real. LSD (least significant difference) values are listed at the bottom of table columns to indicate whether differences are statistically significant. Bolded values in the overall summary table indicate no significant difference ($p=0.05$) from the top-yielding variety within each column.

Lodging data are very difficult to interpret. A high-yielding variety should not necessarily be downgraded because of a high percentage of lodging for a given year at a given location. Local weather conditions, such as wind and rain, may cause a variety to lodge much more than it normally does. Variety trials normally have a greater degree of lodging than do farmer fields. It should also be emphasized that a variety reported to be 50% lodged does not imply that only 50% of the grain could be harvested. With good equip-

ment, almost all of the grain can often be saved. In 2006, lodging was atypical and occurred primarily at the beginning of heading as a result of weakened stems associated with cold damage. Warm statewide temperatures in January, followed by a severe cold snap in February, is believed to have weakened stems at most locations. Some varieties were more affected and yields were reduced as a result of lodging before grain filling.

Kentucky's climate and soils are well suited for the production of high-quality soft red winter wheat. No single variety has all the desirable characteristics, but each has certain advantages. Yield potential, straw strength and yield, height, heading date, grain quality, disease resistance, and forage potential are important in choosing a variety.

Winter barleys are less winter-hardy than winter wheat but more hardy than winter oats. The degree of winter-hardiness, straw strength, and maturity are important characteristics when choosing a variety. Barley (commercial varieties and experimental hullless lines) performance data are presented in Tables 17 and 18.

2006 Test Conditions

Dry, warm weather during October facilitated timely planting of Kentucky's 2006 wheat crop. Drought-like conditions, which carried through late November, resulted in uneven emergence in some areas of the state. The 2006 small grain variety tests were planted between the 5th and 31st of October. Mild temperatures during January stimulated early growth and development. Single-digit temperatures during the third week of February appeared to have caused some cold damage, which weakened stems and resulted in sporadic premature lodging throughout the state. Overall, insect and disease pressure were low, although powdery mildew was observed throughout the state. Cool temperatures during May with moderate rainfall provided good conditions for grain fill. Dry conditions during early June favored timely harvest and good grain quality.

Acknowledgments

Thanks to the following individuals for their assistance with this project: George Muntz, Bruce and Jeremy Benson, Don Halcomb, Andy Gray, Marty Carraway, Doug Langley, Tim Phillips, Chad Lee, Ron Curd, Dennis Egli, Dottie Call, Marilyn Hooks, Donnie Davis, David Morgan, John James, Letha Drury, and the UK Wheat Science Group.

Ratings

Wheat streak mosaic virus (WSMV), powdery mildew, and rust: 1=excellent, 9=poor.

Head scab: 0=excellent, 100=poor.

* **Head scab** data collected at Lexington Scab Nursery.* **Vomitoxin** (DON) levels and scabby seed (%) data from nurseries will be posted at www.uky.edu/Ag/WheatVarietyTest when available.** **Stripe rust** data collected in 2005.**Powdery mildew** and **leaf rust** data collected at Fayette County test.**WSMV** data collected at Caldwell County test.
