

2009 Summer Annual Grass Report*

G.L. Olson, S.R. Smith, and G.D. Lacefield, UK Department of Plant and Soil Sciences

Introduction

Summer annual grasses provide an important forage crop option for producers in Kentucky. These grasses are mainly used as emergency or supplemental hay and pasture crops, but little information is available on their yield potential. The purpose of this publication is to summarize the University of Kentucky 2007-2009 forage yield trials with sudangrass, sorghum/sudangrass, millets, and teff.

Sudangrass (*Sorghum bicolor ssp. drummondii*) is a rapidly growing annual grass in the sorghum family. It is medium yielding and well suited for grazing or hay because of its smaller stem size. Sudangrass regrows quickly after harvest and can be grazed several times during summer and early fall.

Sorghum x sudangrass hybrids are more vigorous and slightly higher yielding than sudangrass. A larger stem size makes these hybrids less useful for hay, therefore they are commonly used for baleage and grazing.

Pearl millet (*Pennisetum glaucum*) is the most widely grown type of millet. It is well adapted to production systems characterized by drought, low soil fertility, and high temperature. It is higher yielding than foxtail millet and regrows rapidly after harvest if an 8- to 10-inch stubble height is left. Dwarf varieties, which are leafier and better suited for grazing, are available.

Foxtail (German) millet (*Setaria italica*) is shorter growing and finer stemmed than pearl millet. This makes it easier to harvest as hay. However, it is the lowest yielding of the summer annual grasses and will not regrow to produce another harvest. It is a good smother crop to be used before late summer no-till seeding of another forage crop such as fescue or alfalfa. It is also used

in wildlife plantings to produce food and cover for doves, quail, and other birds.

Teff, also referred to as summer lovegrass (*Eragrostis tef*), is a warm season annual grass native to Ethiopia and has been used as a grain crop for thousands of years. Recently, there has been considerable interest in teff as a forage crop. It is high quality, palatable, and fine stemmed and therefore makes excellent hay.

Considerations in Selecting a Summer Annual Variety

The major factor in selecting a variety of summer annual grass is yield, both total and seasonal. Growth after first cutting is strongly dependent on available moisture and nitrogen fertilization. Summer annual grasses generally have different characteristics and uses. Pearl millets vary considerably in height and can be used for both pasture and hay. Pearl millet has the advantage of not producing prussic acid (HCN or cyanide). Sudangrass and sorghum-sudangrass hybrids are related grasses (in the sorghum family) and can produce prussic acid immediately after frost or when immature shoots are grazed during severe drought. Sudangrasses are considered to have the least potential for prussic acid poisoning. Sudangrass has smaller, finer stems than sorghum-sudangrass hybrids, which have finer stems than forage sorghums. Consequently, sudangrasses are more easily cured for hay. Pearl millets, sudangrass, sorghum-sudangrass, and teff are typically harvested multiple times during the growing season, and foxtail millet is harvested only once. For more detailed management recommendations refer to *Producing Summer Annual Grasses for Emergency or Supplemental Forage* (AGR-88), and *Teff*, which can be found at www.uky.edu/Ag/Forage under "Publications" in the "Grass" species.

Description of the Tests

This report summarizes studies at Lexington (one in 2007, two in 2008 and three in 2009) and Princeton (one in 2008 and one in 2009). The soils at Lexington (Maury) and Princeton (Crider) are well drained silt loams and are well suited to annual grass production. Plots were 5 ft x 20 ft in a randomized complete block design with four replications with a harvested area of 5 ft x 20 ft. All trials were sown into a prepared seedbed using a disk drill at the following rates (pounds/acre): sudangrass (25), sorghum-sudangrass (30), pearl millet (20), foxtail millet (20), and teff (5 for uncoated, 8 for coated). Plots were harvested with a sickle-type forage plot harvester. Cutting height was 4 inches for the millets and teff and 6 inches for sudangrass and sorghum-sudangrass. Fresh weight samples were taken at each harvest to calculate percent dry matter production. All tests were managed for establishment, fertility, pest control, and harvest according to University of Kentucky Cooperative Extension Service recommendations. Pests were controlled so that they would not limit yield. Nitrogen was applied at 60 pounds per acre two weeks after planting and 30 pounds/acre immediately after the first harvest.

Results and Discussion

Weather data for Lexington and Princeton are presented in Tables 1 and 2.

Yield data (on a dry matter basis) for all tests are reported in Tables 3 through 10. Varieties are listed in order from highest to lowest total production. Yields are given by cutting and as a total for the year. Statistical analyses were performed on all yield data to determine if the apparent differences are truly due to variety or just due to chance. Varieties not significantly different from the highest numerical

*Includes trials planted in 2007 and 2008.

value in a column are marked with one asterisk (*). To determine if two varieties are truly different, compare the difference between the two varieties to the Least Significant Difference (LSD) at the bottom of the column. If the difference is equal to or greater than the LSD, the varieties are truly different when grown under the conditions at a given location. The Coefficient of Variation (CV), which is a measure of the variability of the data, is included for each column of means.

Low variability is desirable and increased variability within a study results in higher CVs and larger LSDs.

Summary

Summer annual grasses can be an important supplemental source of pasture, hay, and silage in Kentucky. Varieties should be selected for their seasonal and total yield characteristics and for their suitability for the method of harvest to

be employed (pasture, hay, or silage). Make sure seed of the chosen variety is properly labeled and will be available when needed.
